The millions of different chemical compounds that make up everything on Earth are composed of 118 elements that bond together in different ways. This module explores two common types of chemical bonds: covalent and ionic. The module presents chemical bonding on a sliding scale from pure covalent to pure ionic, depending on differences in the electronegativity of the bonding atoms.

Ionic Bonding When two elements of very different groups in the Periodic Table react (e.g., the metals Na and Mg from Groups 1 and 2 on the left side with the nonmetals O<sub>2</sub> and Cl<sub>2</sub> from Groups 6 and 7 on the right side), the product is a solid (usually colorless) that has a high melting point. The product is an insulator but will conduct electricity in the molten state.

Probably the most famous of the organometallic compounds is the exceedingly stable orange ferrocene, [Fe(C<sub>5</sub>H<sub>5</sub>)<sub>2</sub>]. Its discovery in 1951 triggered an explosion in coordination chemistry, and the subsequent preparation of thousands of new organometallic compounds. Ferrocene consists of two planar, five-membered rings sandwiching an iron atom between them.
